Significant changes have taken place in the policy landscape surrounding cannabis legalization, production, and use. During the past 20 years, 25 states and the District of Columbia have legalized cannabis and/or cannabidiol (a component of cannabis) for medical conditions or retail sales at the state level and 4 states have legalized both the medical and recreational use of cannabis. These landmark changes in policy have impacted cannabis use patterns and perceived levels of risk. However, despite this changing landscape, evidence regarding the short- and long-term health effects of cannabis use remains elusive. While a myriad of studies have examined cannabis use in all its various forms, often these research conclusions are not appropriately synthesized, translated for, or communicated to policy makers, health care providers, state health officials, or other stakeholders who have been charged with influencing and enacting policies, procedures, and laws related to cannabis use. Unlike other controlled substances such as alcohol or tobacco, no accepted standards for safe use or appropriate dose are available to help guide individuals as they make choices regarding the issues of if, when, where, and how to use cannabis safely and, in regard to therapeutic uses, effectively. Shifting public sentiment, conflicting and impeded scientific research, and legislative battles have fueled the debate about what, if any, harms or benefits can be attributed to the use of cannabis or its derivatives, and this lack of aggregated
knowledge has broad public health implications. The Health Effects of Cannabis and Cannabinoids provides a comprehensive review of scientific evidence related to the health effects and potential therapeutic benefits of cannabis. This report provides a research agenda—"outlining gaps in current knowledge and opportunities for providing additional insight into these issues"—that summarizes and prioritizes pressing research needs.

At the last Annual Representative Meeting of the British Medical Association a motion was passed that "certain additional cannabinoids should be legalized for wider medicinal use." This report supports this landmark statement by reviewing the scientific evidence for the therapeutic use of cannabinoids and sets the agenda for change. It will be welcomed by those who believe that cannabinoids can be used in medical treatment. The report discusses in a clear and readable form the use and adverse effects of the drug for nausea, multiple sclerosis, pain, epilepsy, glaucoma, and asthma.

Medical cannabis is currently legal in 29 states. Of those, none provide insurance coverage for the substance. This leaves consumers in a difficult situation: choose to purchase cannabis at their own expense or choose a potentially more harmful or addictive pharmaceutical medication covered by insurance. The dilemma is not new, but consumers and entrepreneurs alike are creating inventive ways to deal with the problem. Microdosing has become one of the most popular and effective options for treating illness without taking on a hefty medical bill. Dr. Dustin Sulak covers the topic extensively in both his medical practice and in numerous online journals. According to Dr. Sulak, "For most medications, a higher dose will result in a stronger therapeutic effect and a higher likelihood of adverse effects; this is described as a monophasic dose-response relationship. Cannabis simply does not follow this pattern." His research concluded that after a certain point, higher dosages can actually result in weaker therapeutic effects and an increase in negative side effects. The lowest effective dose tends to be the most therapeutic. A 2012 study published in The Journal of Pain treated three groups of cancer patients with variable doses of THC and CBD. The group receiving a lower dose experienced a more significant reduction in pain than the group receiving the higher dose. Those receiving the highest
dose had the same decrease in pain as the placebo group, but experienced more adverse effects.

Although primarily used today as one of the most prevalent illicit leisure drugs, the use of Cannabis sativa L., commonly referred to as marijuana, for medicinal purposes has been reported for more than 5000 years. Marijuana use has been shown to create numerous health problems, and, consequently, the expanding use beyond medical purposes into recreational use (abuse) resulted in control of the drug through international treaties. Much research has been carried out over the past few decades following the identification of the chemical structure of THC in 1964. The purpose of Marijuana and the Cannabinoids is to present in a single volume the comprehensive knowledge and experience of renowned researchers and scientists. Each chapter is written independently by an expert in his/her field of endeavor, ranging from the botany, the constituents, the chemistry and pharmacokinetics, the effects and consequences of illicit use on the human body, to the therapeutic potential of the cannabinoids.
